Delft University of Technology

exam – **Embedded Software** – TI2726-B

April 15, 2016 13.30 - 15.00

This exam (6 pages) consists of 60 True/False questions.
Your score will be computed as: $\max(0, \frac{\#correct}{60} - \frac{1}{2}) \times 2 \times 9 + 1$
It is **not** allowed to consult the book, handouts, or any other notes.

Instructions for filling in the answer sheet:

- You may use a **pencil** (erasures are allowed) or a **pen** (blue or black, **no** red, **no** strike outs).
 - Fill in the boxes **completely**.
 - Answer **all** questions; there is no penalty for guessing.
 - Do not forget to fill in your **Name** and **Student Number**, and to **sign** the form.
-

The following abbreviations are assumed to be known:

- FQS (Function Queue Scheduling)
- ISR (Interrupt Service Routine)
- RR (Round Robin)
- RRI (Round Robin with Interrupts)
- RTOS (Real-Time Operating System)

One system clock tick = 10 ms (unless stated otherwise).

We make use of the following definitions:

```
void delay(int ms) {  
    !! do some CPU computation to the number of ms milliseconds  
}  
  
void putchar(char c) {  
    while (!! UART tx buffer not empty)  
        ;  
  
    !! send c to UART tx buffer  
}  
  
void puts(char *s) {  
    !! write string s using putchar  
}
```

1. Embedded programming is more difficult than “classical” programming because of the higher level of abstraction involved. true/false
2. A defining characteristic of embedded systems is the restricted, or complete lack, of a user interface. true/false
3. Despite advances in software engineering practices, as a rule of thumb, embedded software contains 1-10 bugs per million lines of code. true/false
4. An embedded program can be coded as a finite state machine where all state transitions are triggered by user actions. true/false
5. Finite State Machines can be coded in VHDL.
- An advantage of doing so is that it results in lower interrupt latency as less context (e.g., registers) need to be saved and restored. true/false
6. A software interrupt is an asynchronous signal to indicate the need for a change in the execution flow. true/false
7. Besides Finite State Machines other models of computation suitable for embedded systems include Symbolic Execution and Discrete Events. true/false
8.

```
typedef void *resolve(void *old, void *new);
```

The definition above declares the prototype of the function `resolve`, which takes two arguments of type `void *` and returns a void pointer as result. true/false
9. Valgrind is programming tool that aids memory debugging.
- it does so by executing a program in a safe environment. true/false
10. The C language is centered around the `int` data type, which is defined to hold integral numbers of at least 16 bits. true/false
11. Finite State Machines can be coded in a number of ways in C.
- In the table-based solution, every transition (arc) is encoded as a separate function. true/false
12.

```
int main(void)
{
    int c;
    statefp state = before;
    while((c = getchar()) != EOF) {
        state = (statefp) (*state)(c);
    }
    return 0;
}
```

The above driver loop for a FSM is interrupt based. true/false
13. Specifying the type of `statefp` is difficult in C because forward declarations are not supported for function types. true/false
14. Using interrupts improves system response time. true/false
15. An interrupt service routine should restore the context upon exit. true/false

16. To guarantee atomicity interrupts must be disabled. true/false

17. An ISR can **not** be interrupted by another ISR. true/false

18.

```
static int iSeconds, iMinutes;
void interrupt vUpdateTime(void)
{
    ++iSeconds;
    if (iSeconds>=60) {
        iSeconds=0;
        ++iMinutes;
    }
}
long lSeconds(void)
{
    disable();
    return (iMinutes*60+iSeconds);
    enable();
}
```

Despite disabling interrupts the above pseudo code fails to solve the shared-data problem. true/false

19. By structuring a program as a collection of tasks the data sharing problem is resolved. true/false

20. An interrupt vector table contains the code of the interrupt service routines. true/false

21. The worst-case latency for servicing an interrupt is a combination of factors, including the time taken for higher priority tasks. true/false

22. Given the following pseudo code, which reads the current values of 3 different buttons and acts accordingly. The 3 buttons are all mapped to bits 0..2 of the button register. The buttons are already debounced.

```
void f1(void) { delay(1000); }
void f2(void) { delay(2000); }
void f3(void) { delay(3000); }

void main (void) {
    while (1) {
        if (buttons & 0x01) f1();
        delay(1000);
        if (buttons & 0x02 ) f2();
        delay(1000);
        if (buttons & 0x04 ) f3();
    }
}
```

This code is an example of an RR architecture. true/false

23. When none of the buttons have been pressed, the longest time that button #2 must be pressed to activate f2() once is 1 second. true/false

24. When the system is in an arbitrary state, button #1 must be pressed at most 7 seconds to activate f1(). true/false

25. **Priority inversion** requires a minimum of 3 tasks of different priority and 3 semaphores to occur. true/false
26. A **deadly embrace** requires a minimum of 2 tasks and 1 semaphore to occur. true/false
27. Shared variables marked `volatile` guarantee atomic access. true/false
28. With an RR architecture, the handling of an I/O device may need to wait until all other devices have been served. true/false
29. An RRI architecture supports priority-based ISRs. true/false
30. The response time to an external event in an FQS architecture depends on the longest task in the system. true/false
31. Consider an alarm system that constantly monitors the digital output of several motion detector sensors in a house. If a breach is detected then an intermittent alarm sound is triggered.
- To guarantee a minimum response time an FQS architecture must be used. true/false
32. The **primary** shortcoming of an RRI architecture is that critical sections must be used. true/false
33. An FQS architecture has a smaller memory footprint than an RTOS as it needs only one stack. true/false
34. In an RTOS, tasks can be in state BLOCKED, READY or RUNNING.
- A task can transition directly from BLOCKED to READY. true/false
35. Semaphores can be used for signaling between ISRs. true/false
36. A reentrant function may **not** reference variables labeled `extern`. true/false
37. A semaphore used for guaranteeing mutual exclusive access to shared resources must be initialized to 1. true/false
38. A high-priority task must **not** invoke an RTOS function that may block. true/false
39. An ISR may call the `OS_post()` routine, provided that the RTOS “knows” that the invocation is by an ISR and not by an ordinary task. true/false
40. The ‘alternating buffers’ technique addresses the shared-data problem by copying the data from the in- to the out-buffer instead of passing a pointer. true/false
41.

```
int f (int x) {
    disable_int();

    !! read some global variables
    !! do some processing, call some functions
    !! write some global variables

    enable_int();
}
```
- Function `f()` disables/enables interrupts to address the shared-data problem.
- However, when `f()` calls itself recursively, it is no longer reentrant. true/false

42. Given is the following RTOS (pseudo) code with priority $T1 > T2$.

```
void T1(void) {
    while (1) {
        OS.Pend(sem1); // event #1 may unblock any time
        f(1);
    }
}

void T2(void) {
    while (1) {
        OS.Pend(sem2); // event #2 may unblock any time
        f(-1);
    }
}

void f(int i) {
    delay(10); // do some computation
    counter = counter + i ; // modify some global counter
    printf("%d\n", counter) ; // print result
}
```

- The function `f()` is reentrant. true/false
43. If count is set to 15 when event 2 occurs, and event 1 follows 3 ms later, then the first value printed is 16. true/false
44. If the call to `delay` is replaced with `OSTimeDly` the order of the print statements depends on whether or not a timer interrupt appeared in between the two events. true/false
45. An RTOS usually provides two types of delay functions: polling-based and timer-based.
- timer-based delays are more efficient as other tasks can run while the caller is waiting for the specified time to pass. true/false
46. The **heartbeat timer** is a single hardware timer an RTOS is using to verify that the system is still progressing (i.e. not deadlocked). true/false
47. Assume that one system clock tick = 10 ms.
- Calling the function `OSTimeDly(6)` causes a delay between 65 and 75 ms. true/false
48. To address the shared-data problem, many RTOSs provide communication primitives like queues, mailboxes, and pipes.
- a common pitfall is that they allow pointers to be passed from one task to another. true/false
49. Even when an RTOS is aware of which task is using which semaphore, it cannot prevent deadlock. true/false
50. Time-slicing should be avoided in an RTOS because it makes the response time of tasks less predictable. true/false
51. The minimal memory footprint of a program grows linearly with the number of tasks. true/false
52. Printing from an ISR is to be avoided except when the RTOS provides a reentrant primitive to do so. true/false

53. Time slicing between tasks of equal priority is common practice in embedded systems. true/false
54. Aborting tasks is nontrivial because a task may hold resources (e.g., a semaphore) when being destroyed. true/false
55. Tasks should have different priorities to avoid fairness issues imposed by the RTOS. true/false
56. Code coverage tools help in thorough testing.
- a 100% coverage implies a bug-free program. true/false
57. A logic analyzer is preferred to an in-circuit emulator because it is easier to install; not all signals need to be connected. true/false
58. Debugging through scripting test scenarios can only be used to test HW-independent code. true/false
59. A large study of outdoor sensor-network deployments [Beutel:2009] has shown that the two most underestimated problems have been the water-proof packaging of the sensor nodes and the provision of a reliable base station. true/false
60. When debugging code for a distributed sensor network, collecting the (debug) output of the nodes can be arranged in different ways.
- A **wireless** testbed requires **no** physical instrumentation (i.e. wiring) of the sensor node. true/false
